1. Reconstruct the niche

Although job changes are vital for economic growth, we knew very little about how workers move between different industries or how industry-specific their skills are. Earlier measures focused mainly on the trade supply chains or shared locations, and they were ignoring if industries actually require similar worker skills. The authors examine the patterns, stability, and regional effects of job changes across industries. They build a new skill-relatedness index based on worker flows, proving that industry-specific skills matter greatly. This new index predicts local industry entry and growth much better than traditional measures.

2. 2 journal articles

Csáfordi, Zs., Lőrincz, L., Lengyel, B., & Kiss, K. M. (2020). Productivity spillovers through labor flows: productivity gap, multinational experience and industry relatedness. *The Journal of Technology Transfer*, *45*(1), 86–121.

- The authors extend Neffke et al.'s (2017) concept of skill-relatedness to examine productivity spillover effects in the Hungarian economy, showing that the efficiency of knowledge flow through labor mobility depends on the productivity gap between sending and receiving firms and on multinational corporate experience.

Sánchez-Moral, S., Vale, M., & Arellano, A. (2022). Skill-Relatedness and Regional Economic Development in Spain during the International Crisis and the Post-Crisis Period. *Papers in Regional Science*, *101*(3), 573–602.

- Using data from Spain, the study examines the labor-based connectivity indicators proposed by Neffke et al. (2017). They are extending their analysis to the context of the macroeconomic shocks of the economic crisis and the subsequent recovery period in order to assess their impact on regional economic resilience and structural change.

3. Own niche

Previous researches show that worker movement between industries predicts the regional growth, but we do not know that how the green transition will change these labor flows. This matters because the policymakers have to know if local workers have the appropriate skills for new green jobs or the skill shortages will hold back the transition. In this case, I would state a research question, something like the following: To what extent do workers moving to green jobs follow traditional job-change patterns, and which industry shifts face the biggest skill barriers?

4. Database

KSH microdatabase or the Eurostat database (containing individual-level employment histories, job classifications (like FEOR), wages, industry classifications over a long time series). It would be useful for policy makers, regional policy authorities, who are planning regional industrial development strategies in order to support the green transition.
