1. The paper addresses a research gap regarding labor mobility between industries and hypothesizes that there is a structure in inter-industry labor flows determined by human capital relatedness and skill-requirement. Building on the assumption that human capital is industry-specific to some extent, it asks whether inter-industry labor flows reveal a structure of skill relatedness and whether this structure can help explain regional economic development. Instead of asking one specific question the paper aims to lay down the foundations of analyzing the labor market through the lens of a skill-relatedness network. For validation it shows that the network is stable over time, similar across different worker groups and largely independent of geographical distance between jobs. The labor-flow based measure outperforms other existing ones in predicting industry growth and entry rates because they fail to directly capture similarities in human capital requirements, only determining the relatedness based on location, export or input-output.

2. **McDowall et al. (2023), Mapping regional vulnerability in Europe's energy transition**
   The paper uses the idea of industry-specific skill relatedness to map the economic vulnerability of European regions planning to cut back on their carbon-intensive industries. They use the findings of Neffke, Otto & Weyh (2017) to explore the impact of differences in skill transferability across carbon-intensive industries on regions' ability to adapt.

   Diodato, Hausmann & Neffke (2023), The impact of return migration on employment and wages in Mexican cities
   This paper also builds on the idea of industry-specific human capital but puts it in an international context and analysis the impact of returning migration from the US in Mexico. It extends the economic theory further by stating that workers coming home influence the labor market of Mexico and cause structural changes in the countries industry.

3. When I did my first homework I stumbled upon a rather interesting dataset - the Brazilian Agricultural Census from 2017- which does include data on agricultural workers but unfortunately, it is cross sectional so we cannot estimate labor flows based on it. What grabbed my attention was that it also includes data on informal employment. So, my gap statement would be the following: "Previous work has shown that formal workflows between industries follow a pattern, but we do not know how people transition between informal and formal jobs. This matters because informal employment is particularly widespread in agriculture in developing countries and understanding how workers move between formal and informal jobs could help policymakers design better policies to encourage formal employment and prevent workers from falling back into informality." A great research question could be**: Does skill relatedness between industries influence agricultural workers' chances of moving from informal into formal employment in Brazil?**
4. Fortunately, there is not only one dataset on Brazilian agricultural workers so I can recommend for the policy makers to use the PNAD Contínua — Brazilian National Household Sample Survey, which includes information on formal and informal employment, industry, occupation and follows household for at least 5 quarters.
